CPITN / bleeding), plaque index, tooth mobility, OHIP, HADS and a visual analog pain scale was performed.

Results and Conclusions: they will be presented at the Congress.

Objective: To study the relationship between HPV and oral leukoplakia lesions by pathological and immunohistochemical samples.

Material and Method: A descriptive study with data obtained from 138 biopsies corresponding to 78 patients histologically diagnosed leukoplakia in the unit of Oral Medicine at the University of Santiago de Compostela was carried out. The presence of viral DNA was performed by two system CLART®HPV (Genomics, Madrid, Spain) by polymerase chain reaction (PCR).

Results: Data from 43 biopsies corresponding to 30 patients were obtained. Histopathological analysis revealed 39 cases of leukoplakia (varying degrees of hyperplasia and hyperkeratosis), 2 COCE and 2 of warty carcinoma. Leukoplakia lesions showed absence of dysplasia in 26 cases (60.4%) and dysplasia in 13 (30.2%) (mild in 7 samples, moderate in 1 and severe / carcinoma in situ 5). Of the 43 biopsies could only isolate viral DNA in 10 samples being found varying degrees of dysplasia.

Conclusion: The presence of HPV DNA appears to show a statistically significant relationship with clinical lesions (size, location or number of lesions) characteristics, however other relationship is observed regarding the age of patients, particularly those over 65.

TITLE: Clinic pathological study of patients with proliferative verrucous leukoplakia over 60 years

Master de Medicina Oral, Cirugía Oral e Implantología. Facultad de Odontología. Universidad de Santiago de Compostela.

* doi:10.4317/medoral.17644000
http://dx.doi.org/10.4317/medoral.17644000

Objectives: knowing the effectiveness of CO2 laser treatment of leukoplakia lesions in 20 patients over 65 years.

Material and Method: A transversal epidemiological study was made in the Master of Oral Medicine, Surgery and Implantology of the University of Santiago de Compostela of patients diagnosed with oral leukoplakia, whom underwent a biopsy and subsequent CO2 laser vaporization. All of them were evaluated the following variables: shape, sex, location, single / multiple lesion, size, power, smoker, drinker, age and power.

Results: Only 25% of our patients achieved a complete resolution of the lesion.
