Introduction: The proliferative verrucous leukoplakia (PVL), initially described by Hansen in 1985; LVP is a precancerous lesion of unknown origin, slow growth, warty, exophytic, durable and irreversible appearance, begins as a simple benign hyperkeratosis, which tends to spread, becoming a multifocal lesion, possibly becoming malignant and present a high mortality rate in developing carcinoma because of the propensity for dysplasia and malignant. It has a higher incidence in older women, where the primary lesion (leukoplakia) is present for many years.

Case report: We report a case of a female patient of 75 years old, non-smoker, does not drink alcohol, carrier upper and lower dentures, diagnosed in 1994 homogeneous leukoplakia and lichen planus, I will perform monitoring and controls in the department of medicine and orofacial surgery UCM, where non homogeneous lesions (red and white areas level right tuberosity, and warty level tuberosity left type white areas) is observed in 2016, new biopsy was performed in April this year, resulting homogeneous leukoplakia transformation to proliferative verrucous leukoplakia.

Conclusions: The LVP has a high rate of malignant and very unpredictable, for this reason the need for periodic checks are very important, and thus diagnose early, its evolution malignant carcinoma.

TITLE: Zirconium implants, the immediate future in implantology?.

AUTHORS: García Polo E, Nunes Pereira F.
Clinica Caser Dental.

* doi:10.4317/medoral.17644105
http://dx.doi.org/10.4317/medoral.17644105

Excellence in our profession is a constant and for that reason there are new developments. We aproach this review the use of zirconium implants in clinical day by day.

Ceramics are different chemical compounds to metals. Zirconium is a high performance ceramic. The advantages are: high biocompatibility (allergic to metal choice), aesthetics (recessions and gingival smiles, thin soft tissue), high osseointegration >98% in clinic (surface treated with laser decreases colonization and reabsorption), excellent mechanical properties (tense flexural, tore up to 70 Ncm anterior and posterior teeth) and it also does not suffer corrosion. Radiopaque material, with the possibility of intraoral carved after placement and immediate loading with provisional, very aesthetic.

The monobloc system avoids the “gap” that can bring about bone resorption; however if the implants has not primary stability we can not load and we will lose aesthetics.

Material and Methods:
All literature found; research articles and collections of information; onset and evolution until now.

Results:
According to literature, shows a very high standar. In the beginning few studies they thought proved their use; but today is a good choice.

Conclusions:
Guarantee of success; front and especially in posterior teeth, its aesthetics and its histological properties.

Acceptation holistic dentistry to be “free metal”. Material with high guarantees to revoke titanium.

TITLE: Merkel cell carcinoma: a case report

Máster de Odontología en pacientes oncológicos e immunocomprometidos. Facultad de Odontología, Universidad de Barcelona.

* doi:10.4317/medoral.17644106
http://dx.doi.org/10.4317/medoral.17644106

Background: Merkel cell carcinoma (MCC) is an aggressive neuroendocrine tumor that mainly affects the skin. Its incidence is less than 0.5 /100,000 people per year, and has a predilection for the elder. The treatment of election is surgery even though early metastases in distant lymph nodes, followed by distant skin, lung, central nervous system and bone are common. These features give the patients a poor prognosis with a survival rate at 5 years of approximately 50%.

Case report:
We present a 67-year-old male patient with a macula in his right elbow histologically diagnosed as CCM. A year after the diagnosis he developed an oropharyngeal injury that was biopsied, with a diagnosis compatible with CCM, as well as bilateral lymph nodes. The extension study was negative. The patient had the lesion...
